## ■ CMU 17-214 Principles of Software Construction: Objects, Design, and Concurrency

### Principles of Software Construction

Objects, Design, and Concurrency

#### Overview

Software engineers today are less likely to design data structures and algorithms from scratch and more likely to build systems from library and framework components. In this course, students engage with concepts related to the construction of software systems at scale, building on their understanding of the basic building blocks of data structures, algorithms, program structures, and computer structures. The course covers technical topics in four areas: (1) concepts of design for complex systems, (2) object oriented programming, (3) techniques for robustness, including testing and static and dynamic analysis for programs, and (4) concurrent software. Students will gain concrete experience designing and building medium-sized systems. This course substantially improves its students' ability to apply general computer science knowledge to real-world problems using real-world tools and techniques.

After completing this course, students will:

- Be comfortable with object-oriented concepts and with programming in the Java language
- Have experience designing medium-scale systems with patterns
- Have experience testing and analyzing software
- Understand principles of concurrency and be able to build concurrent software
